1. Project Title

Student Performance Analytics System

The Student Performance Analytics System is a Python-based mini-project designed to process and analyze student academic performance using marks and attendance data. It calculates total marks, average marks, grades, pass/fail results, subject-wise statistics, and identifies the top-performing students.

2. Objective

The main objective of this project is to develop a simple data analysis system that helps evaluate student performance efficiently.

The project aims to:

- Read and organize student records from a CSV file.
- Calculate total marks and average marks for each student.
- Assign grades based on average marks.
- Determine pass/fail status using subject marks and attendance.
- Analyze the highest, lowest, and average marks for each subject.
- Calculate overall class statistics and identify the top three academic performers.

This project demonstrates how Python and its data analysis libraries can be used to convert raw student records into meaningful information.

3. Technologies Used

Python: Used to implement the program logic, functions, loops, conditional statements, and data processing.

Pandas: Used to read the CSV dataset, organize records in a DataFrame, filter student records, and display analysis results.

NumPy: Used for numerical calculations, including total marks, averages, and subject-wise statistical analysis.

CSV (Comma-Separated Values): Used as the data storage format for student information, subject marks, and attendance.

Visual Studio Code: Used as the development environment to write, edit, and execute the Python program.

4. Dataset Description

The project uses a CSV file named students.csv, which contains records of 20 students. The dataset stores student details, marks obtained in five subjects, and attendance percentage. It is loaded into a Pandas DataFrame for processing and analysis.

The dataset contains the following columns:

1. Student_ID: A unique identification number assigned to each student.
2. Name: The name of the student.
3. Python: Marks obtained by the student in Python.

The marks for each subject and the attendance percentage are recorded on a scale of 0 to 100. The dataset is used to calculate total marks, average marks, grades, pass/fail results, subject-wise statistics, and the top three academic performers.

5. Implementation

The project is organized into three main files: main.py, functions.py, and students.csv.

Step 1: Loading the Dataset

The Pandas library reads the student records from students.csv using the read_csv() function. The records are stored in a DataFrame and displayed before analysis.

Step 2: Calculating Total and Average Marks

The calculate_totals_and_averages() function extracts subject marks using Pandas and NumPy.

- Total marks are calculated by adding marks across all five subjects.
- Average marks are calculated by dividing the total marks by the number of subjects.
- The calculated values are stored in the DataFrame.

Step 3: Assigning Grades

The assign_grades() function uses conditional statements to assign grades based on each student's average marks.

Average Marks	Grade
90 and above	O
80–89.99	E
70–79.99	A
60–69.99	B
50–59.99	C
40-49.99	D
Below 40	F

Step 4: Evaluating Pass/Fail Results

The evaluate_results() function uses loops and conditional statements to evaluate student results.

A student passes only when all subject marks are at least 40 and attendance is at least 75%. Otherwise, the student is marked as failed.

Therefore, a student can achieve a high grade but still fail because of insufficient attendance or a subject mark below the passing requirement.

Step 5: Performing Subject-Wise Analysis

The get_subject_analysis() function calculates the average, highest, and lowest marks for each subject using NumPy operations.

Step 6: Generating Class Statistics

The main program calculates the total number of students processed, overall class average, number of students who passed, and number of students who failed.

Step 7: Identifying Top Performers

The program sorts students by total marks in descending order and displays the top three academic performers.

The leaderboard is based on total marks, independently of pass/fail status. Therefore, a student who fails due to attendance can still appear among the top three performers.

6. Key Features

The major features of the Student Performance Analytics System are:

1. **CSV Data Loading:** Reads student records from an external CSV file.
2. **Automated Calculations:** Calculates total and average marks for each student.
3. **Grade Assignment:** Assigns grades using predefined average-mark ranges.
4. **Pass/Fail Evaluation:** Checks subject passing marks and minimum attendance.
5. **Class Performance Summary:** Displays the number of students, overall class average, and pass/fail counts.
6. **Subject-Wise Analysis:** Reports average, highest, and lowest marks for each subject.

7. **Top Three Performers:** Ranks students according to their total marks.
8. **Modular Code Structure:** Separates the main program from reusable functions.

7. Output / Screenshots

The program produces a report containing student records, individual performance, class statistics, subject-wise analysis, and the top three academic performers.

         108 Shubham    455     91.0     O
         115 Ruchika    451     90.2     O
         101  Anjali    435     87.0     E
```

8. Final Outcome

The Student Performance Analytics System successfully demonstrates how Python, NumPy, and Pandas can be used to analyze student academic records.

The system processes the student dataset, calculates total and average marks, assigns grades, evaluates results based on marks and attendance, and generates class-level and subject-level statistics.

It also identifies the top three students based on total marks. The project provides a simple and organized way to understand student performance while demonstrating fundamental programming and data analysis concepts.

9. Challenges & Learning

Challenges

During the development and testing process, attention was required to ensure that the CSV file was loaded correctly, the Python files were saved properly, and the output was displayed in the expected format.

Another important aspect was implementing the pass/fail condition correctly so that both subject marks and attendance were considered.

Learning Outcomes

Through this project, I learned:

- How to read and process CSV files using Pandas.
- How to perform numerical calculations using NumPy.
- How to create reusable functions in Python.

- How to use loops and conditional statements to implement decision-making logic.
- How to calculate descriptive statistics and analyze data.
- How to organize a Python project into multiple files.
- How to test a program and interpret its output.

This project strengthened my understanding of Python fundamentals and introduced me to practical data analysis.
